

# Technical Debt Benchmark: Focus where the pain is

Using Data-Driven techniques to reduce friction in Software Development

Javier Gonzalez Huerta

# Who am I?

## Javier Gonzalez-Huerta

Associate Professor in Software Engineering at Blekinge Institute of Technology

- Program Manager: Civilingenjör i Mjukvarutveckling
- >10 years in industry
- PhD in Software Development (Software Engineering)
- Now I'm a researcher / practitioner (not necessarily in that order)
- Collaborate (doing research) with several companies in Sweden:

# But this is a team work...

Dr. Ehsan Zabardast

Senior Researcher at Blekinge Institute of Technology  
Management Consultant at Reinsight

Dr. Binish Tanveer

Associate Senior Lecturer at Blekinge Institute of Technology

Bhuwan Paudel

Ph.D. Candidate at Blekinge Institute of Technology

# Technical Debt?

## Focus where the pain is – Technical Debt Benchmark

# Technical Debt (TD)

- Shortcomings of the TD metaphor?
  - What does it mean to say that we have accumulated 10 years of TD?
  - Everything counts equally?

# Technical Debt (TD)

- Shortcomings of the TD metaphor
  - TD is more tailored for source code related artefacts
  - TD does not consider the TD propagation effects for example between Code and Tests
  - We don't look at it from a system perspective
  - We tend to look at it in isolation

# Limitations of the term TD

- Technical Debt seems a *catch-for-all* to put every negative consequence that happen to our software assets (code, tests, requirements...)
- **“Yes! we have a lot of this...”** is what we hear when we refer to it.

TECHNICAL  
DEBT

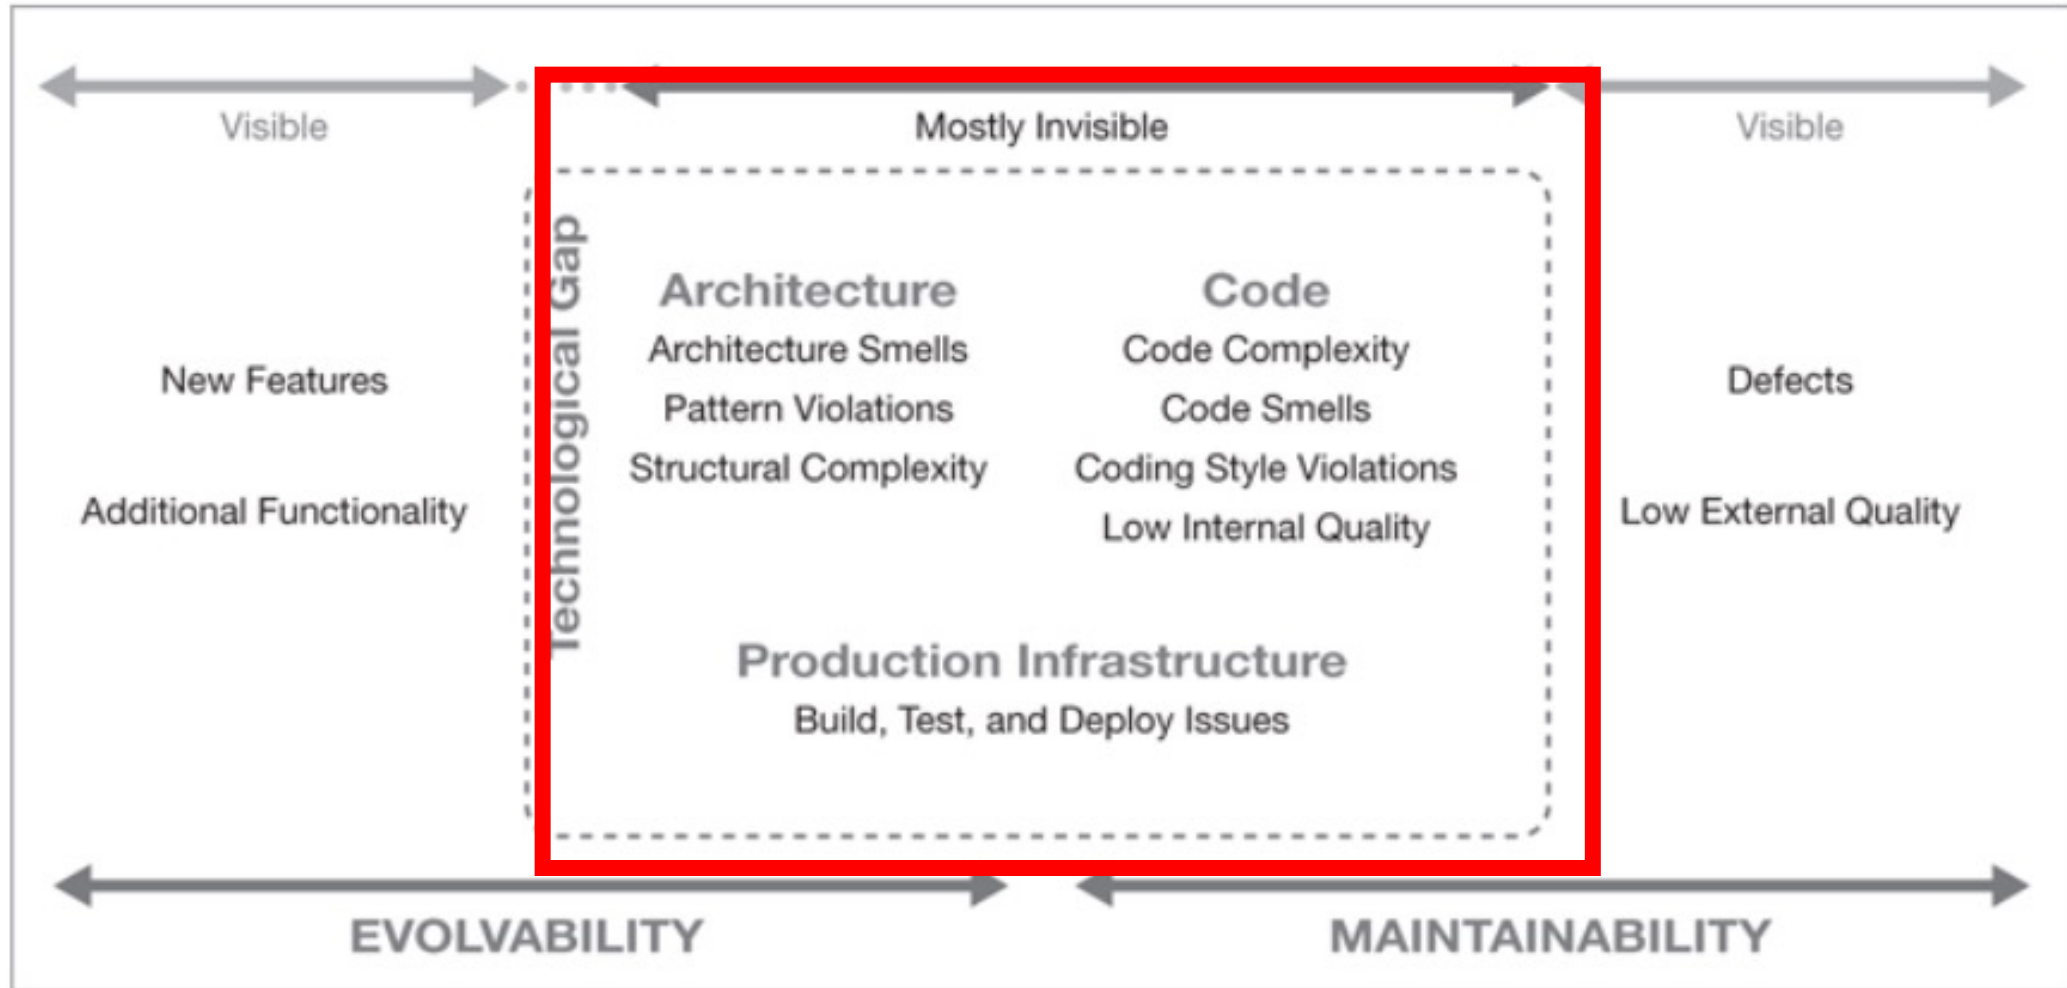

# TD Consequences

**So what?**

# We need to remember...

# From now on...

- I will illustrate the concepts with real examples from the collaborative research we perform with our industrial partners

Company A

Company B

# If we look at it the “normal way”

Apache CloudStack

500/6,585 files

Maintainability Overview ?

Size: Code Smells Color: Maintainability Rating

A B C D E

Zoom: 100%

# But.. Where is the actual pain?

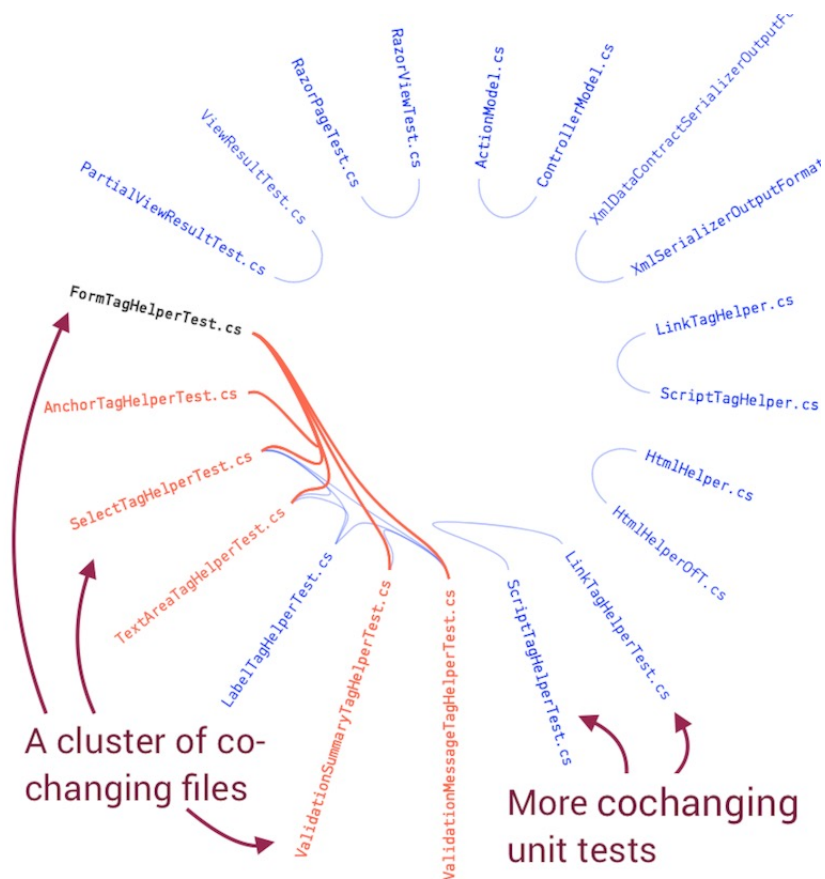

- Not all TD "hurts" the same
- For example: In any system, ~20% of the files take ~80% of the maintenance

Company A

# Making it more complex...

Company A

# At large...

---

# Organization and Architecture

- Looking at the whole system
  - Systems are more than one repository/component
  - Files are not the problem
- Change Cohesion at repository level

Company A

# Organization and Architecture

Node color denotes the team responsible for its quality

Black arrow: code or service dependencies (>5)

LEADING SOFTWARE ENGINEERING

# Software Component Dependencies

Company A

# Software Component Dependencies

## Isolated Repos

- Dependencies are mostly technical
- problems can be addressed easily
- Limited to no propagation of problems

Company A

# Software Component Dependencies

## Borderline Repos

- Repos with smaller dependencies
- Mostly owned by the same team
- Small propagation of problems
- Problems can be fixed with small effort

Company A

# Software Component Dependencies

## Dependency Magnets

- Regardless of the type
- High propagation of problems
- Problems need much more attention

Company A

# Organisational Structures: looking at teams

**REAL SYSTEM**

*Nodes are teams  
Size shows the technical complexity as  
# of dependencies on their repos*

*The closer teams are, the  
more task- and technical-  
dependencies they share*

Company A

Does this create  
friction?

---

# Ownership Misalignment

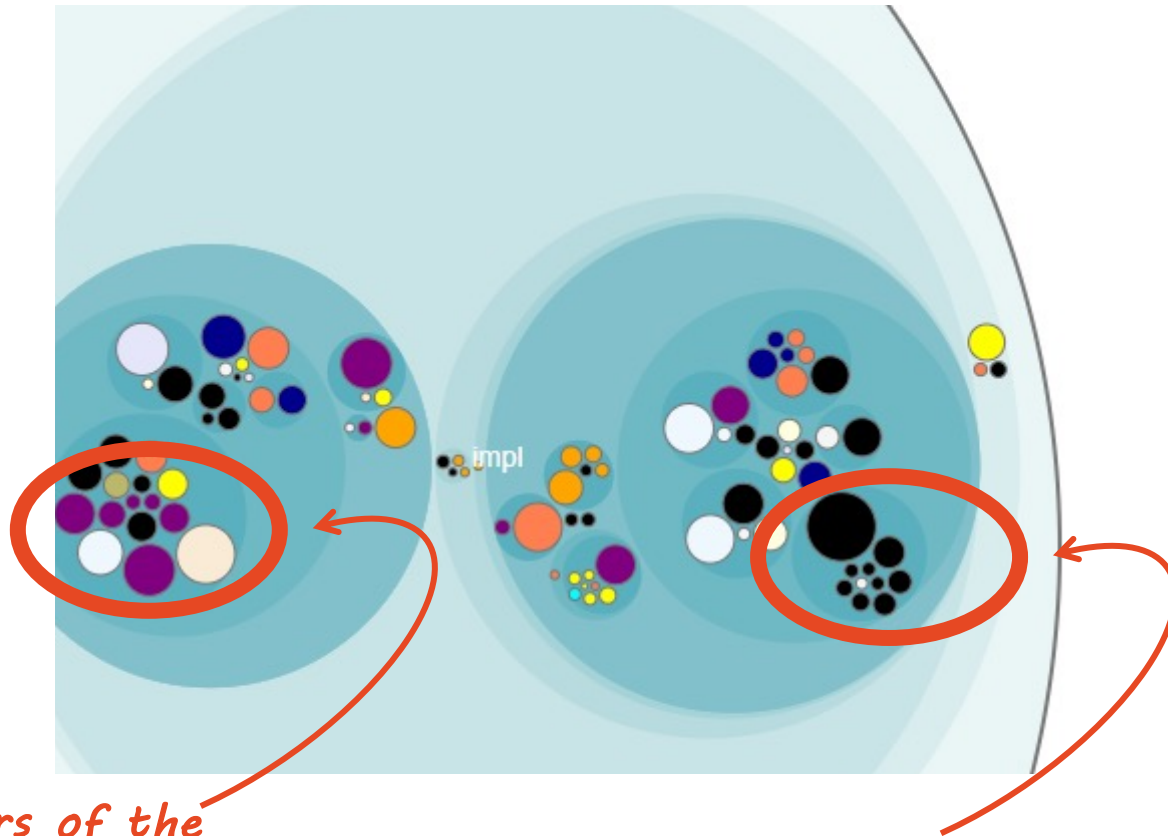

- **Ownership misalignment:** The team that owns a repo is not its *main* contributor

Ehsan Zabardast, Javier Gonzalez-Huerta, & Binish Tanveer. (2022). Ownership vs Contribution: Investigating the Alignment Between Ownership and Contribution. 19th IEEE International Conference on Software Architectures. <https://doi.org/10.1109/ICSA-C54293.2022.00013>

# Responsibility diffusion & lack of ownership

*The colours of the circles denote the team of the main contributor*

*Black circles are code components whose main contributor has left the company*

# Responsibility Diffusion and Knowledge Vaporization

- A high number of teams/individuals contributing might cause *responsibility diffusion*
  - “No one really owns the house, and no one cleans it”
- We can also have knowledge vaporization, due to employees leaving the company

Barley, J. M., & Latanfi, B. (1968). Bystander Intervention in Emergencies: Diffusion of Responsibility. *Journal of Personality and Social Psychology*, 8(4), 377-383.

Tornhill, A. (2015). *Your Code As A Crime Scene*. The Pragmatic Bookshelf. <https://doi.org/10.1017/CBO9781107415324.004>

# Architecture and Organization Alignment: Scenarios

**Scenario A:** Technical Dependency between Repo A and Repo B - No Organizational Dependency (Shared Jira Tickets) - **No harm, beyond complexity**

(c) Ehsan Zabardast & Javier Gonzalez Huerta

Tanveer, B., Zabardast, E., & Gonzalez-Huerta, J. (2023). An approach to align socio-technical dependencies in large-scale software development. International Conference on Software Architecture.

# Architecture and Organization Alignment

**Scenario B:** Technical Dependency between A and B + Organizational Dependency (e.g., Jira Tickets) - **Expected**

If the repos are owned by the different teams, we might incur more time for coordination and PR approval

**Problematic case:** If there are ownership misalignment problems, we (might) add overhead, since there might be a third team involved

(c) Ehsan Zabardast & Javier Gonzalez Huerta

Tanveer, B., Zabardast, E., & Gonzalez-Huerta, J. (2023). An approach to align socio-technical dependencies in large-scale software development. International Conference on Software Architecture.

# Architecture and Organization Alignment

**Scenario C:** No Technical Dependency between Repo A and Repo B - But Organizational Dependency (Shared Jira Tickets) - **Not expected**

If the repos are owned by the different teams, we might incur more time for coordination and PR approval (**longer than in B since the coordination is unexpected**)

**Problematic case:** If there are ownership misalignment problems, we (might) add **even more overhead**, since there might be a third team involved

# But the frictions are not limited to time

- These frictions can also manifest in how fast TD is accumulated
- We are going to talk about this during the last part of the presentation

# Organizational factors and TD

Degree of Ownership and Evolution of TD

# Objective

- We have conducted a study to understand if the degree of contribution can explain how fast or slow TD accumulates
- In this case, we have a formal ownership model:
  - There is a team that is responsible for the quality of each repo
- To see the degree of contribution, we analyse the authors of the code (commits), tickets (Jira), and pull requests (bitbucket).

Company A

# The effect of ownership over TD over time

**REAL SYSTEM**

Company A

# The effect of ownership over TD over time

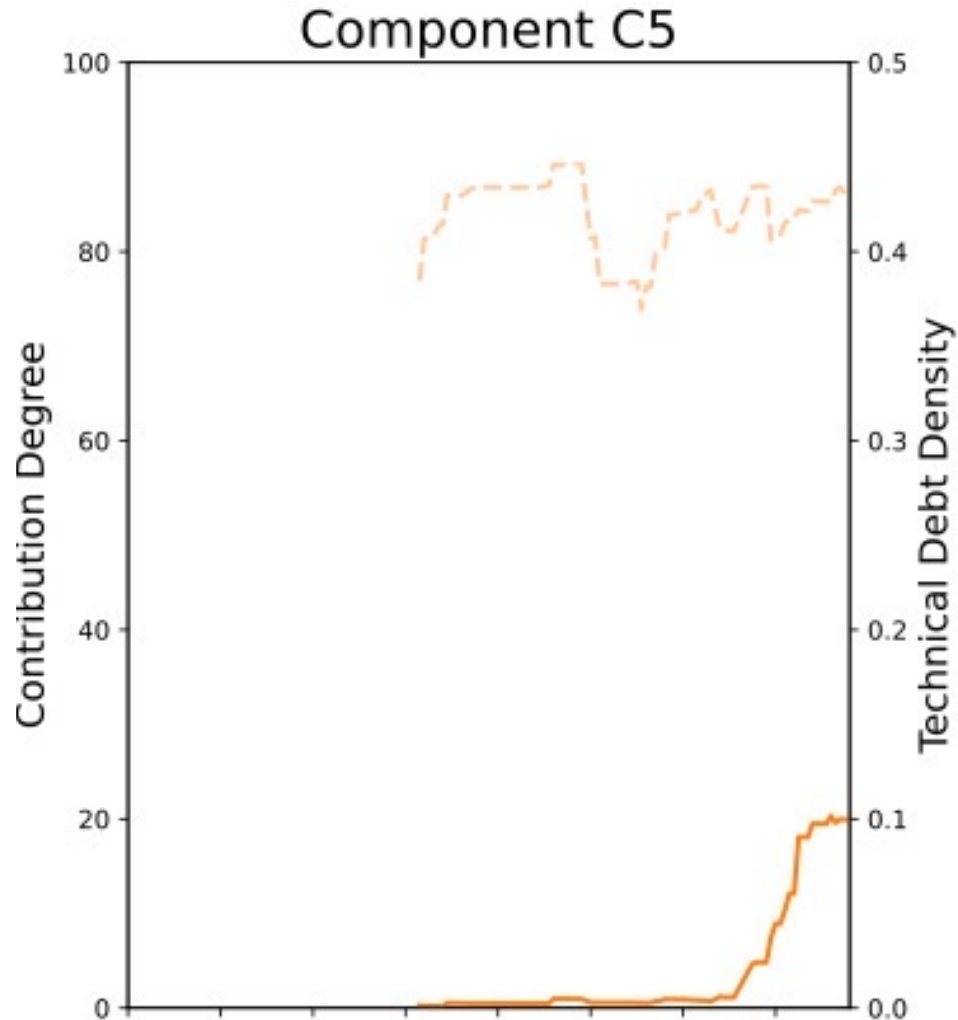

**It seems when contribution goes below a certain level (here <40%), after a period, things tend to go out of control**

Company A

# The effect of ownership over TD over time

**Another observation is that if you "own" everything, you feel more entitled to take risks. This has been sometimes referred as *Technical Credit***

Company A

# Organizational factors and TD

Teams' behaviour when introducing Code Clones

# Objective

- We have conducted a study to understand how different teams behave in different repos when it comes to producing clean code
- As a pilot, we focus on the introduction of code clones
- **Disclaimer:** The quality of the repos we have studied is very high, according to static analysis tools.

# What have we done?

- We mined Git commits to see who committed where
  - In total, we looked at 8 repos during the WFH/Hybrid period 2020-2022
- We look at duplicates before and after each commit
- We calculate statistics to see which teams are contributing to each repo
- We can predict the probability of a team introducing clones

# In a nutshell...

High probability of  
Introducing clones

Probability of any duplicate per team and repository  
added 370 removed 311 complexity 16 duplicates 0

**REAL SYSTEM**

A photograph of a classroom. In the background is a green chalkboard with a wooden shelf below it. On the shelf are two small white erasers and a larger dark grey eraser. In the foreground, a wooden desk holds a blue spiral-bound notebook with a yellow pencil resting on it. A portion of a grey chair is visible on the right.

# So what?

Lessons Learned

## Aligning Architectural and Organisational Structures

---

- **Align formal and actual ownership:** make the team who *knows best* responsible for the quality of that component.
- **Raise awareness of dependencies among teams:** Frequently, teams do not know the teams with which they have strong dependencies (Task & Technical)
- **Solutions are often not technical:** sometimes is not about refactoring the architecture, is about changing teams and responsibilities

A hand is pointing at a bar chart displayed on a tablet screen. The chart consists of seven vertical bars of varying heights, representing data points. The background is a blurred image of a person in a blue shirt.

## Use Your Data!

- Data coming from the tools used in the daily work can assist in decisions to handle TD, focusing where the pain is
- Focus on what causes harm to the process
- Reducing communication overhead and coordination will allow teams focus on what matters
- If teams have a good control on what they are responsible of, will help them prioritise TD repayment
